Field of the Invention The present invention relates to an imaging apparatus including a solid-state imaging device having an overflow drain, to a light-collecting unit, and to an imaging system. 2. Description of the Related Art Conventionally, in many electronic appliances, a CCD (charge coupled device) or MOS (metal oxide semiconductor) image sensor which is one of solid-state imaging devices is often used. In the solid-state imaging device such as a CCD image sensor, when a light-collecting unit for collecting lights generated by photoelectric conversion is in contact with a semiconductor substrate, the semiconductor substrate is charged due to electrical interference. As a result, an abnormality occurs in the solid-state imaging device, which makes it impossible to output an image signal. For this reason, it is necessary to drain the semiconductor substrate and prevent the semiconductor substrate from being charged. The overflow drain technology is one means for achieving the foregoing. A solid-state imaging device having an overflow drain is proposed in, for example, Japanese Patent Laid-Open No. 11-192213.Q: Understanding 2D Perlin Noise In the perlin noise tutorial the final result is multiplied by a random number. The random number could be outside the interval [0,1], but the final result is not. Why is this? This question, while similar, is not quite about the same as the one I am asking, but still closely related. A: From the example I assume you're familiar with the concept of "rendering", where in order to make some primitive visible we need to add some lighting, and we do it by adding some constant factor (the brightness) to every point that is visible, no matter what that point's actual color is. This means that all points get brighter, but by how much is determined by the current lighting. To determine how much to increase, we add together all the brightnesses of 3e33713323
